

Description of the Experiment

While wearing an EEG-cap, participants will engage in a computer-based control detection task where they try to figure out which of the two moving images is the one they are partially controlling. After the control detection task, they will engage in a surprise recognition memory task where they will be asked whether they have or have not seen certain images. The entire experimental session will take approximately 2.5 hours, including EEG preparation and clean-up. The aim of the study is to elucidate the processes involved in the detection of control and its effect on recognition memory.

Expense Calculation

Item	Value
Compensation per hour	9.00 Euro
Experiment duration	2.5 hours
Compensation per participant	$9 \times 2.5 = 22.50$ Euro
Planned number of participants	30
Total Compensation Amount Requested	$22.50 \times 30 = 675.00$ Euro
